HYPERKALAEMIA

RECOGNITION AND ASSESSMENT
- Plasma potassium >6 mmol/L (normal 3.0-5.5 lithium heparin specimen)
- Neonates often tolerate concentrations up to 7.5-8.0 mmol/L without ECG changes

SYMPTOMS AND SIGNS
- Cardiac arrest
- ECG abnormalities (see below):
  - tall peaked T waves
  - widened QRS complex
  - sine waves
  - bradycardia

Causes
- Renal failure: secondary to hypoxic ischaemic encephalopathy (HIE), sepsis and hypotension, or structural abnormalities
- Very low-birth-weight babies without renal failure (non-oliguric hyperkalaemia) in first 12–48 hr
- Excess K+ in IV solutions

INVESTIGATIONS
- If sample haemolysed, repeat and send free-flowing venous sample or arterial sample
- If potassium >6.0 mmol/L, connect to cardiac monitor

IMMEDIATE TREATMENT
Serum potassium >6.0 mmol/L (stable with normal ECG)
- Stop all K+ IV solutions or oral supplements
- Reconfirm hyperkalaemia
- Institute continuous ECG monitoring

Serum potassium >7.0 mmol/L without ECG changes
- As above
- Give salbutamol 4 microgram/kg IV in glucose 10% over 5-10 min: effect evident within 30 min but sustained benefit may require a repeat infusion after at least 2 hr
  - if IV access difficult, give nebulized salbutamol 2.5 mg as a single dose (difficult to administer if ventilated and not formally evaluated in neonates) and repeat if necessary
- Give intravenous insulin 0.5 units/kg in sodium chloride 0.9% and 25% glucose 5 mL/kg both over 30 min: very effective and has an additive effect with salbutamol
- Repeat U&E
- Repeat infusion as necessary until K+ <7 mmol/L
- Monitor blood glucose every 15 min for first 2 hr during and after infusion
  - aim for blood glucose 4-7 mmol/L

Serum potassium >7.5 mmol/L with ECG changes
- As above, but first institute emergency measures below:
  - give 10% calcium gluconate 2 mL/kg IV (diluted with equal volume glucose 10%) over 5-10 min
  - flush line with sodium chloride 0.9% or preferably use a different line
  - give intravenous sodium bicarbonate (1 mmol/kg over 2 min) this is effective even in patients who are not acidotic (2 mL of 4.2 % sodium bicarbonate = 1 mmol)
Further treatments: discuss with consultant
- A cation-exchange resin, such as calcium resonium (500 mg/kg rectally, with removal by colonic irrigation 8-12 hrly, repeat every 12 hr. Dose can be doubled at least once to 1 g/kg in severe hyperkalaemia), useful for sustained reduction in serum potassium but takes many hours to act and is best avoided in sick preterms who are at risk of NEC (necrotizing enterocolitis)
- If severe hyperkalaemia persists despite above measures in term babies with otherwise good prognosis, contact renal team for consideration of dialysis
- Exchange transfusion using fresh blood or washed red blood cells provides another strategy for sustained and reliable reduction in serum K⁺ concentration

SUBSEQUENT MANAGEMENT
- Recheck serum K⁺ 4-6 hrly; when arrhythmias present with renal failure, monitor hrly
- Monitor urine output and maintain good fluid balance
- If urine output <1 mL/kg/hr, unless baby volume depleted, give furosemide IV 1 mg/kg until volume corrected
- Treat any underlying cause (e.g. renal failure)

Consequences

Figure: Hyperkalaemia leads to tall, peaked T waves, ventricular arrhythmias, widening of QRS, then sine wave QRS complex (before cardiac arrest)
